COMPONENTS

WHAT IS A REACT COMPONENT?

- A component is an **independent, reusable code block**, which divides the UI into **smaller pieces**.
- In other words, we can think of components **as LEGO blocks**. Likewise we create a LEGO structure from many little LEGO blocks, we create a webpage or UI from many little code blocks (components).

FUNCTIONAL(STATELESS) COMPONENT

- React has 2 types of components: Functional (Stateless) and Class (Stateful).

```
function App() {  
  return (  
    <div>  
      <Clothes name="Quần jean" type="Skinny" color="Đen" size="L">Jean</Clothes>  
      <Clothes name="Váy" type="váy Dạ hội" color="Trắng" size="M">Đầm</Clothes>  
    </div>  
  );  
}
```

functional component

You, a few seconds ago • Uncommitted changes

React Functional Component:

- is a JavaScript / ES6 function
- must return a React element
- take props as parameter if necessary

FUNCTIONAL(STATELESS) COMPONENT

- React has 2 types of components:
Functional (Stateless) and Class (Stateful).

The simplest way to define a component in React is to write a JavaScript function

```
function Welcome(props) {  
  return <h1>Hello, {props.name}</h1>;  
}
```

```
class Welcome extends React.Component {  
  render() {  
    return <h1>Hello,  
      {this.props.name}</h1>;  
  }  
}
```

REACT CLASS COMPONENT

A React class component

- Is **an ES6 class**, will be a component once it **'extends'** React component.
- can accept **props** (in the constructor) if needed
- can maintain **its own data with state**
- must have a **render()** method which **returns a React element (JSX)**, or null.

CLASS (STATEFUL) COMPONENT

13

- Class components are ES6 classes.
- They are more complex than functional components including constructors, life-cycle methods, render() function and state (data) management.

```
import React, { Component } from 'react';

class ExampleComponent extends Component {
  render() {
    return (
      <div>This is an example component.</div>
    );
  }
}

export default ExampleComponent;
```

FUNCTIONAL(STATELESS) COMPONENT

14

Functional component is basically a JavaScript (or ES6) function which returns a React element.

```
import React from 'react';
import ReactDOM from 'react-dom';
import './index.css';

function UserInfo(props) {
  component as
  function
}

ReactDOM.render(
  document.getElementById('root')
);
```

WHY COMPONENT?

15

- We don't really want to have thousands of lines of code together in one single file. Maintenance of the code gets more and more complex as the project gets bigger.
- Solution : **dividing the source code into components helps us a lot.**
- Each component has its own JS and CSS code, they are reusable, easier to read, write and test.

HOW TO CREATE AND CALL A COMPONENT

16

- React functional component as a **JS Function**

```
function Example() {  
  return ( <h1>I'm a functional component!</h1> );  
};
```

or as an ES6 arrow function

```
const Example = () => {  
  return ( <h1>I'm a functional component!</h1> );  
};
```

Both of the functions are valid React components.

COMPONENT BASED

BUILDING BLOCK OF REACT

React helps us break up applications into reusable, self-contained components.

DATA + UI

Components combine view logic, user interface, and data.

COMPOSITION

We can combine multiple components to form complex apps.

REACT COMPONENTS

18

CLASS COMPONENTS

Component written using a
JavaScript Class.....

Until recently, many important
React features only worked in
class component

FUNCTION COMPONENTS

Component written using a
JavaScript Function....

Until recently, function component
were reserved for very simple
components.

CLASS COMPONENTS

19

```
class CounterClassBased extends React.Component {  
  constructor(props) {  
    super(props);  
    this.state = { count: 0 };  
    this.decrement = this.decrement.bind(this);  
    this.increment = this.increment.bind(this);  
  }  
  
  decrement() {  
    this.setState({ count: this.state.count - 1 });  
  }  
  
  increment() {  
    this.setState({ count: this.state.count + 1 });  
  }  
  
  render() {  
    return (  
      <div>  
        <div>Current count: {this.state.count}</div>  
        <div>  
          <button onClick={this.decrement}>-</button>  
          <button onClick={this.increment}>+</button>  
        </div>  
      </div>  
    );  
  }  
}
```

HOOKS-BASED COMPONENT

20

```
function Counter() {  
  const [ count, setCount ] = useState(0);  
  
  return (  
    <div>  
      <p>count: {count}</p>  
      <button onClick={() => setCount(count+1)}>Add</button>  
      <button onClick={() => setCount(count-1)}>Subtract</button>  
    </div>  
  );  
}
```

TYPE OF DATA IN REACT

21

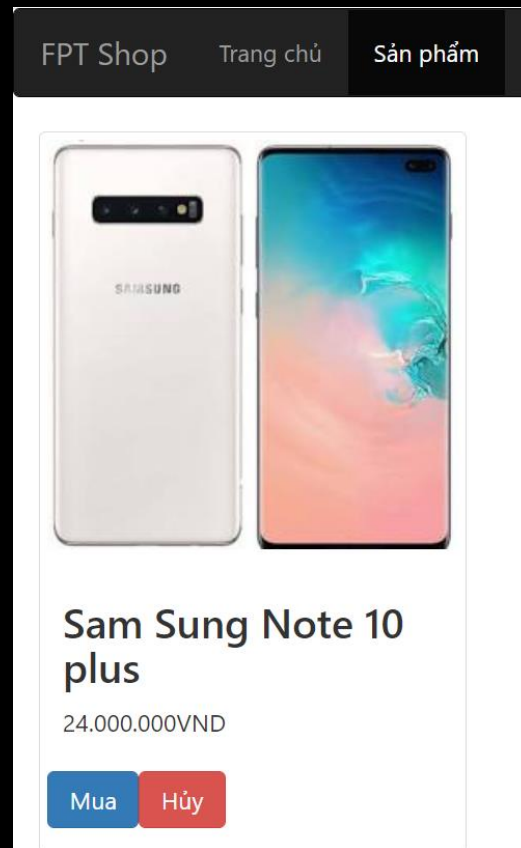

State :

- A variable that can be updated.
- Used to implement “Reactivity”
- Used to trigger a Re-render.
- Responsible for all the interactivity of the app.

DEMO: CREATE REACT COMPONENT

22

- STEP 1 : I will create 1 **class** component, as **parent** component
- STEP 2: And 1 **functional** component as **child** component
- STEP 3: call the child inside the parent component
- STEP 4: Finally, call the parent component on the **root file (app.js)**
